## Preface

This report describes application of the Hydrologic Engineering Center Flood Damage Analysis (HEC-FDA) programs used in the Omaha District, Corps of Engineers, Readiness Management System demonstration project below Oahe Dam on the Missouri River. The project applied Geographic Information System (GIS) data, processed and stored using the Geographic Resources Analysis Support System (GRASS), to generate much of the input data to the flood damage programs. The raster formatted data included land use (damage categories), reference flood, topographic, and damage reach boundary variables. The HEC-DAMCAL program used the data to develop, and store in HEC-DSS, elevation-damage and elevation-number of structure relationships by category and damage reach and elevation-crop area relationships by damage reach. These relationships were subsequently retrieved by the HEC-PBA program to generate urban and crop flood damage by damage reach, state, and congressional district boundary.

Thomas Johnson, on developmental assignment to HEC from the Omaha District, was the principal engineer on the project. Omaha District staff provided the GIS data. Staff from the Construction Engineering Research Laboratory (CERL), Corps of Engineers, assisted with the GRASS applications. Donna Lydon, Bob Carl, Dick Fong, and Marilyn Hurst from HEC assisted in various aspects of the study. Loshan Law was responsible for the final report preparation. Michael Burnham, Chief of the Planning Analysis Division, HEC, provided general guidance. Darryl Davis was Director of HEC during the conduct of the study.

# **Flood Damage Analysis within the Readiness Management System**

## **1. Introduction**

### **1.1. Readiness Management System**

The Readiness Management System (RMS) was developed for the Corps of Engineers' Emergency Management offices. The system provides near real-time assessments of the impacts associated with rainfall-runoff, tributary inflows and the operation of Corps reservoirs during emergency situations. The RMS utilizes Geographic Information System (GIS) technology combined with hydrologic, hydraulic and flood damage programs. The system enables users to estimate effects of reservoir operation and tributary inflows on flow conditions for specific stream reaches given various operation scenarios.

The need for the RMS became evident because of an inability to assess downstream impacts during previous dam safety exercises performed by the Omaha District. The damages and/or benefits associated with various operation scenarios were estimated from generalized damage curves. At that time, there was no means of quickly modeling reservoir releases to estimate potential damages. As a result, the potential damages considered as part of the decision making process were crude and lacked adequate support.

Although decisions on reservoir operation are not made by a single entity, the advantages of having a single system as a basis for decision making are numerous. These advantages include:

- A common data base utilized by those involved in the decision making process provides more consistent results.
- More realistic estimates of impacts associated with various reservoir releases by modeling releases using a realistic flood damage model.
- Detailed graphics capabilities within the GIS allow decision makers to quickly visualize flood boundaries and areas impacted.
- Higher degree of confidence in decisions that are made because of increased reliability from using analytical techniques.
- Better documentation of the decision making process because all of the information used in the analysis is stored and can be retrieved at any time.

The primary advantage of having an RMS is the fact that all offices, both Federal and State, are using the same system as a basis for their actions. Once a system is accepted as the standard, it serves as a common basis for making decisions during an actual

emergency. The utilization of a standardized system also provides a means for checks and balances because everyone using it should be getting approximately the same results.

## 1.2. Flood Damage Analysis

The Hydrologic Engineering Center (HEC) adapted flood damage programs for use in the RMS primarily to provide near real-time estimates of flood damages for specific events. Some of the data needed to compute flood damages was developed using a Geographical Information System (GIS). The Geographic Resources Analysis Support System (GRASS), developed by the U.S. Army Corps of Engineers, Construction Engineering Research Laboratory (CERL), was chosen as the GIS software to be used in the RMS.

HEC used existing flood damage programs with some minor modifications. The Damage Reach Stage-Damage Calculation (HEC-DAMCAL) and Project Benefit Accomplishment (HEC-PBA) programs were adapted for use in the RMS. The Data Storage System (HEC-DSS) is also used in the RMS as a means of storing, manipulating and transferring information. The four major software components used in flood damage calculations are:

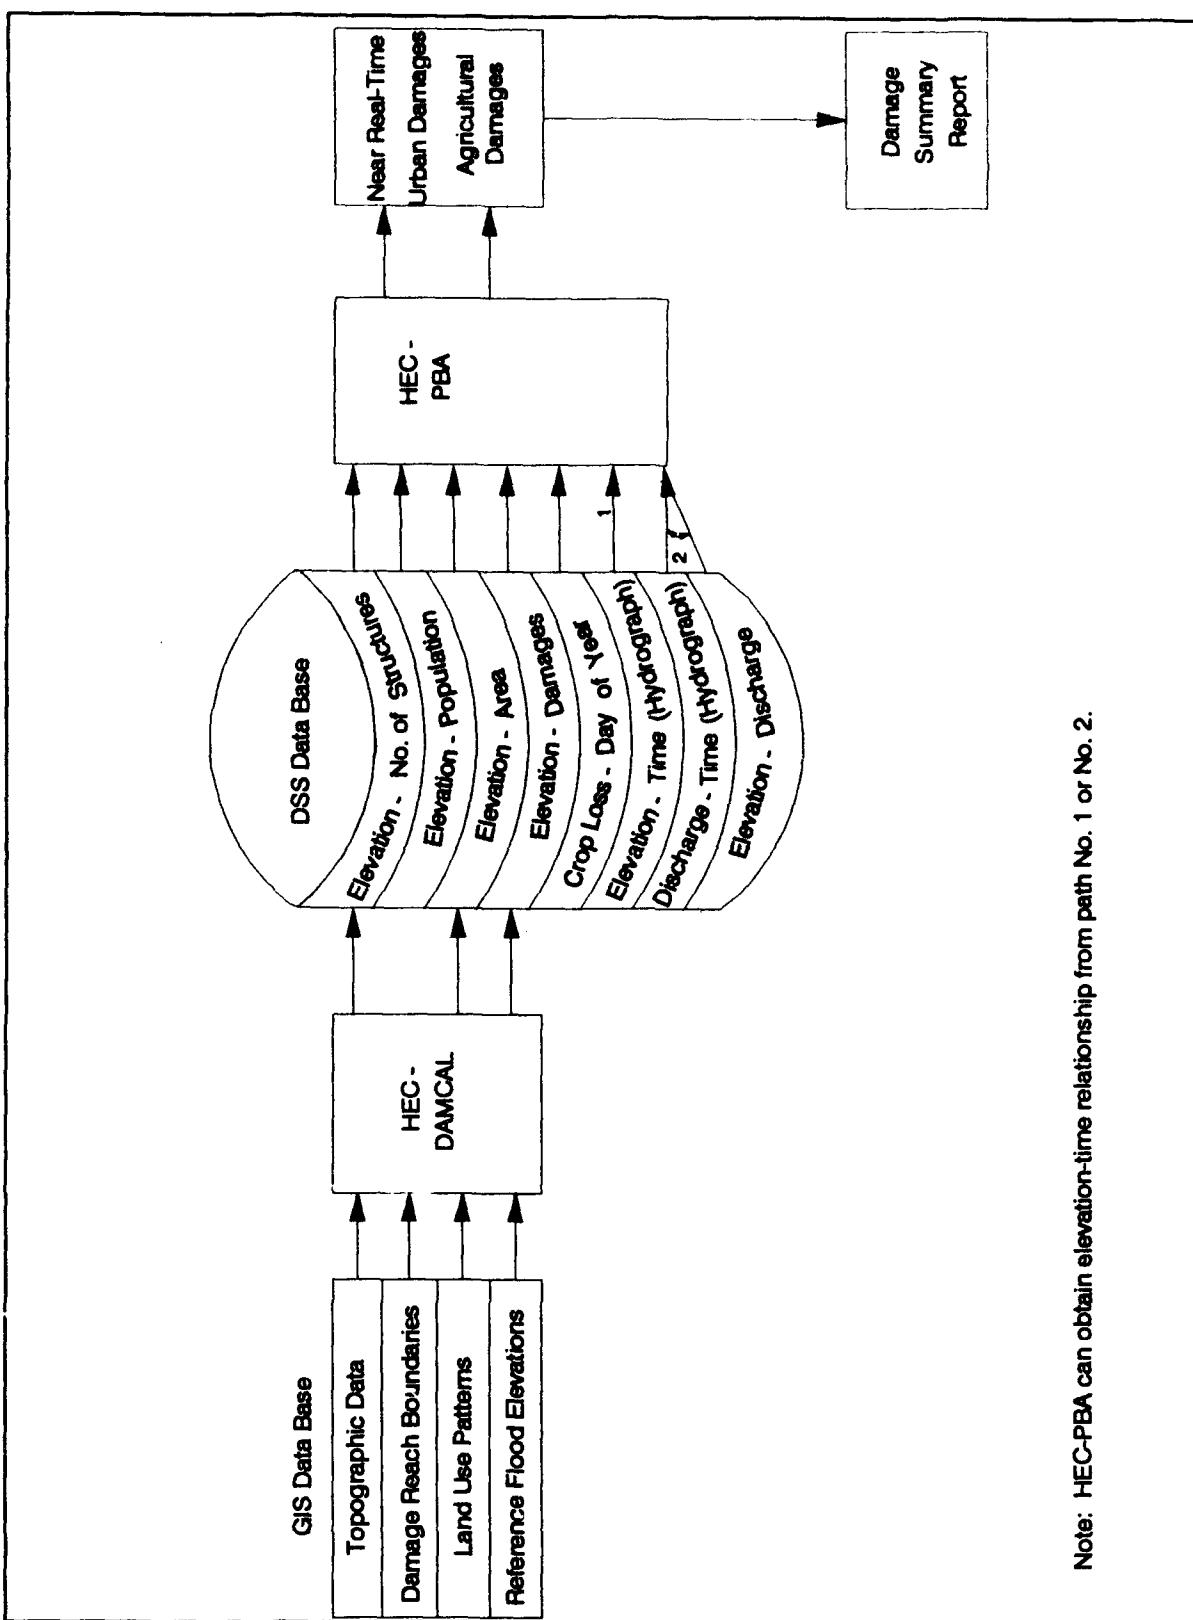

- (1) The GRASS GIS package
- (2) The HEC-DAMCAL program
- (3) The HEC-DSS package
- (4) The HEC-PBA program

Figure 1 is a schematic representation of the how the flood damage analysis components interact within the RMS. The following paragraphs describe the operation of each component.

**(1) Geographic Resources Analysis Support System,** GRASS was developed by the U.S. Army Corps of Engineers, Construction Engineering Research Laboratory (CERL). GRASS was chosen as the GIS software for the RMS and is useful for analyzing and displaying spatial data related to flood damage analysis. The program can be used to generate a data base file which contains information for each grid cell. The attributes listed in the data base file are necessary for calculating flood damages using the HEC-DAMCAL program.

**(2) Damage Reach Stage-Damage Calculation,** HEC-DAMCAL was developed in the mid 1970's as part of a family of computer programs designed to provide a systematic technique for managing and analyzing spatial data for use in water resources management investigations. The program accesses data stored in a grid cell data base. A more detailed description of how the HEC-DAMCAL program operates is contained in the DAMCAL users manual and is available from the Hydrologic Engineering Center (U.S. Army Corps of Engineers, February 1979).

HEC-DAMCAL has the ability to evaluate damages for existing or future land use conditions. The program also has the ability to evaluate damages associated with:

**FIGURE 1** Flood Damage Package

Note: HEC-PBA can obtain elevation-time relationship from path No. 1 or No. 2.

- nonstructural alternatives such as flood plain management policies,
- flood proofing alternatives (raising structures or adding flood resistant materials to structures),
- permanent evacuation of structures in the floodplain, and
- any combination of the preceding.

Damage Reaches. HEC-DAMCAL operates on the assumption that all water surface profiles are parallel throughout a damage reach which is one of the basis for the reach delineation. Therefore, the user must evaluate a range of water surface profiles for a study area and define damage reaches that satisfy that criteria as nearly as possible while maintaining the economic detail desired for analysis. After the damage reach boundaries have been chosen, they are encoded into the grid cell data base by assigning each grid cell a damage reach identification number.

The program aggregates elevation-damage relationships from each grid cell within a damage reach to an index location. The index location can be anywhere in the reach. Total damages for a reach are reported based on elevations at the index location.

Reference Flood. In order to account for slope in the water surface profile of a reach, HEC-DAMCAL defines the relationship between flooding at each grid cell and flooding at the index location. This is done by use of the reference flood. The program assumes that all floods are spatially distributed the same as the reference flood. A reference flood is best defined by a hypothetical frequency flood event in the mid range of damage potential. Reference flood water surface elevations must also be encoded into the grid cell data base by assigning a water surface elevation for each cell. If a flood larger than the reference flood is to be analyzed, the reference flood boundaries must be extended to include the entire area of interest. Therefore, some grid cells may have a reference flood elevation which is actually lower than the ground elevation.

Computations. The user must develop an input file for HEC-DAMCAL which defines the format of the grid cell data base, composite damage functions for each land use category, and flood elevations at the index location for each damage reach. Composite damage functions define the potential structural and nonstructural damages for a range of flood depths for each land use category. Flood elevations at the index locations can be specified for single flood events such as the 50-, 10-, 2-, or 1-percent chance exceedance frequency events.

The program assigns a stage-damage relationship to a grid cell based on the land use (damage category) specified and the composite damage function for that particular land use. The stage is converted to elevation the grid cell by setting the zero stage equal to the first floor elevation of the structure. HEC-DAMCAL then aggregates the elevation-damage relationship of each cell by damage category to the index location by adjusting the elevation scale based on the difference in the reference flood elevations. The damages are reported separately for each land use. Land use categories can also be aggregated into a single elevation-damage relationship for the damage reach. If single flood events are specified, the program calculates damages for those events based on the water surface elevations at the index location.

If the user wants to determine what effect flood proofing would have on reducing damages within a reach, they need only specify the land use categories to be flood proofed

and the elevations at the index location below which no flood damage would occur. Similarly, the effects of removing contents (evacuation) can be estimated by specifying the land use categories to be evacuated.

HEC-DAMCAL also calculates elevation-area flooded relationships using the same techniques described previously. Total area flooded within a reach is likewise based on the water surface elevation for a given flood event at the index location. It should be noted that when a user specifies a damage category (land use) to be flood proofed, they are flood proofing all grid cells with that land use classification. Consequently, the area flooded should be determined for non flood proofing conditions.

Another item in which the user may be interested in is the number of structures in each land use category flooded by a single event. HEC-DAMCAL can calculate the elevation-structures flooded relationship by simply defining the average density (structures/developed area) and the percent of the total area that is developed, for each land use category. The number of structures flooded is also based on the flood elevation at the index location.

**(3) Project Benefit Accomplishment, HEC-PBA** was developed to determine damages prevented (benefits) by existing Corps projects. The program is currently undergoing modifications and has not yet been officially released. A detailed description of the program operation will be contained in the HEC-PBA users manual and will be available from the Hydrologic Engineering Center in the near future.

The HEC-PBA program enables the user to calculate damages to both urban and agricultural areas on a near real-time basis. The program accounts for damages which may have occurred from a previous flood event by using a "look-back" routine. By accounting for any previous damages and time to rebuild in an urban area, the program determines a more realistic value for damages from a single flood event. For agricultural areas the program accounts for previous flood events based on time required for the land to dry out and whether there is sufficient time to replant the crop. If the farmer has experienced a previous flood and replanted, the program also accounts for any reductions in the expected yield. The look-back time period can be several years or a few months, depending on the users preference.

**Damage Reaches.** HEC-PBA calculates damages based on damage reach definitions. The program does not perform calculations on individual grid cells. Damage reaches are often defined for urban areas and agricultural areas separately. HEC-PBA uses a special crop damage routine which analyzes agricultural damages differently than urban damages.

The damage reach definitions must also be consistent with jurisdictional boundaries. HEC-PBA is able to report damages based on several different boundary definitions such as community, State, County, and Congressional districts. The program aggregates damages for all of the reaches within a specified jurisdictional area. Therefore, it is important that damage reaches do not overlap a boundary line.

**Crop Loss Functions.** A significant advantage of the HEC-PBA program is its sophisticated crop damage analysis capabilities. The program accounts for the type of crop, planting season, growing season, time to harvest and average yield per acre. Crop damages are calculated based on the time of year that a flood occurs and duration of flooding. The

damage is based on a reduction in the expected yield caused by flooding. Dollar values are then assigned to the lost yield based on expected market values for the crop. Total damages also include losses associated with investments in crop production at the time of the flood.

The program uses crop loss functions to define the relationship between time of the year and potential impacts to crops should flooding occur. Each type of crop has a unique crop loss function. The relationship is based on the percentage of a crop that would be lost due to flooding for both the timing and duration aspects. The program does not account for the depth of flooding and its effects on different crops.

**Computations.** The user must develop an input file for HEC-PBA which defines the jurisdictional boundaries, damage reaches, crop characteristics, reconstruction time, and period of analysis. Crop loss functions for each crop must also be developed. HEC-PBA obtains the elevation-damage and elevation-area relationships from HEC-DAMCAL. The program is not intended to interface directly with the GIS data base.

HEC-PBA calculates damages using hydrograph data which specifies the flood elevation and time of year the flood occurs. If a hydrograph contains several months of data and more than one flood event exceeds the zero damage elevation, the user must specify the event for which damages are calculated by defining the starting and ending dates of the analysis. A look-back date can be specified prior to the starting date to account for previous events. This establishes the potential damage status at the beginning of the analysis.

Urban damage calculations are based on elevation-damage relationships and hydrograph information. Each damage category is analyzed separately within a damage reach. Agricultural crop damage calculation are based on elevation-area relationships, hydrograph information, and crop loss functions. Each crop type is analyzed separately within a damage reach.

The HEC-PBA program also calculates the number of structures flooded by a single event for each land use category. Closely related to the number of structures flooded is the number of people affected. However, the population affected depends a great deal on the time of day and the day of the week on which the flood occurs. HEC-PBA does not account for these population variations. The program does accept input of elevation-population relationships which are intended to represent a measure of people impacted by a flood.

**(4) Data Storage System,** HEC-DSS is used for the flood damage analysis within the RMS to transfer information from HEC-DAMCAL to HEC-PBA. The HEC-DSS utility programs used in conjunction with the flood damage programs are: DSSUTL, DISPLAY, REPGEN and DSSPD.

**DSSUTL.** The DSSUTL program provides a means of performing utility functions on data stored in HEC-DSS. These functions include tabulating, editing, copying, renaming, and deleting data. The program also offers the capability of formatting and copying data into an ASCII sequential file for transfer to another computer, or for use by a program without HEC-DSS capabilities.

DSPLAY. The DSPLAY program enables a graphical display of data contained in an HEC-DSS file. Time-series and paired data can both be displayed. Up to seven curves and six different y-scales may be displayed at one time. The program is useful for visualizing the data generated by HEC-DAMCAL to verify that the results are reasonable. It is also useful to view the crop loss functions to be used by HEC-PBA and verify that the curves are consistent and meaningful.

REPGEN. The report generator, REPGEN, is used to simplify and automate the production of routine reports. REPGEN provides for the retrieval and presentation of data from an HEC-DSS file or text file on a pre-specified, user defined, fixed format. The format is the equivalent of a blank form onto which variable information is entered in designated locations.

DSSPD. The DSSPD program provides a means of entering paired function data into an HEC-DSS file. The crop loss functions used in HEC-PBA are paired data functions that relate percent crop loss to days of the year. They can be entered into HEC-DSS using the DSSPD program.

## 2. System Installation

### 2.1. Directory and File Structure

The flood damage analysis package for the Omaha District RMS was set up with four directories. Each directory contains specific files. It is important that these directories be created prior to installation. The required directories are:

- (1) HECEXE
- (2) RMS
- (3) DAMCAL
- (4) PBA

(1) The HECEXE directory contains all of the executable versions of HEC programs. The HEC programs needed for flood damage computations within the RMS are;

- COED.EXE - Corps editor used for file editing.
- DAMCAL.EXE - Flood damage calculation model for GIS data.
- DRIVERS.EXE - File to manage display drivers.
- DSPLAY.EXE - DSS program for graphical displays.
- DSSPD.EXE - DSS program for entering paired data.
- DSSTS.EXE - DSS program for entering time series data.
- DSSUTL.EXE - DSS program for editing DSS records.

- MATHPK.EXE - Program for manipulating DSS records.
- PREPBA.EXE - Preprocessor program for PBA
- PBA.EXE - Flood damage and benefit calculations.

(2) The RMS directory contains all of the screen, macro and batch files necessary for operation of the RMS menu screens. All files with no extension are batch files that are substituted into one of the TEMP.BAT files when needed. Files with a BAT extension are normal batch files. Files with a MAC extension are macro files used by the PREADR program to evoke different responses when choices are made within the menu screens. Files with an SCN extension are screen files used by PREADR to display the menu screens.

(3) The DAMCAL directory contains the input and output files necessary for operation of the HEC-DAMCAL program. This directory also contains the HEC-DSS file and the macro and batch files used to reformat the DSS records. *It is essential that the names of these files always remain the same in order for the menu selections to operate properly.* The following is a list of the files in the DAMCAL directory:

- MISSOURI.DSS - HEC-DSS file which contains all of the DSS records output from HEC-DAMCAL and records to be used as input to HEC-PBA.
- MOAGRI.DC - Input file used by HEC-DAMCAL to compute damages in agricultural areas.
- MOAGRI.DCO - Output file from HEC-DAMCAL for agricultural areas.
- MOURBAN.DC - Input file used by HEC-DAMCAL to compute damages in urban areas.
- MOURBAN.DCO - Output file from HEC-DAMCAL for urban areas.
- \* ● AGRISTAT.GDB - Grid cell data file containing attribute information for grid cells in agricultural areas.
- \* ● URBSTAT.GDB - Grid cell database file containing attribute information for grid cells in urban areas.

\* NOTE - The files with a GDB extension are generated on the workstation using the GIS. The RMS flood damage analysis package was developed to allow the GDB files to remain on the workstation and be accessed automatically through a local area network. If a network is not available, it will be necessary for these files to be copied and installed on the PC.

(3) The PBA directory contains the input and output files necessary for operation of the HEC-PBA Preprocessor and Analysis programs. *It is essential that the names of these files remain the same in order for the menu selections to operate properly.* The following is a list of files in the PBA directory;

- PREPBA.IN - Input file for the HEC-PBA Preprocessor program.
- PREPBA.OUT - Output file from the HEC-PBA Preprocessor program.
- PBA.IN - Input file for the HEC-PBA Analysis program.
- PBA.OUT - Output from the HEC-PBA Analysis program.

## **2.2. Installation Procedure**

The installation procedure is generally similar to installation of other HEC products. As previously mentioned, the appropriate directories must be created prior to installation and files placed directly in those directories. The installation disks contains the same directories and files as will be needed on the PC. It is important that all files are copied from each directory on the disk to directories of the same name on the PC. The PKUNZIP program is used to decompress those files with a ZIP extension.

It will also be necessary to load GSS device drivers for producing graphical displays with the DSPLAY program. The installation instructions and diskettes are provided separately. The installation of drivers is menu driven and user friendly.

This product has minimum hardware requirements because of the amount of computing required. It may also be necessary to modify the AUTOEXEC.BAT and CONFIG.SYS files on the PC prior to beginning operation. The following sections describe the requirement and necessary modifications.

**(1) Hardware Requirements.** This product was developed using a 486/33C personal computer with 8 MB's of extended memory. The HEC-DAMCAL, MATHPK, and HEC-PBA programs all require extended memory. The programs will not operate properly if the EMM 386 memory manager is being used.

It is recommended that this product be installed on nothing less than a 386/25C computer with a math coprocessor and at least 3 MB's of extended memory. The DSPLAY program requires a minimum of 450K of resident memory, with the device drivers loaded, to operate properly. In most instances it will be necessary to have all network software unloaded while running DSPLAY. This product was designed to have the network software running only during operation of the HEC-DAMCAL program.

**(2) AUTOEXEC.BAT Modifications.** The AUTOEXEC.BAT file must contain the following statements:

PATH C:\HECEXE - The HECEXE directory must be listed in the path statement.

SET CGIPATH=C:\GSS - Statement to define the directory in which the device drivers are located.

**(3) CONFIG.SYS Modifications.** The CONFIG.SYS file must contain the following statements:

DEVICE=C:\DOS\ANSI.SYS - To allow display of the menu screens.

LASTDRIVE=Z - Needed if a fictitious drive is created to allow access to data on the workstation.

### **3. Flood Damage Computations**

#### **3.1. Overview of Computational Procedure**

Calculation of the potential flood damage within the Readiness Management System (RMS) framework relies on the Geographic Information System (GIS) to provide input data for the HEC-DAMCAL program. HEC-DAMCAL generates relationships between water surface elevations and the damages, number of structures, and total area that could be flooded. These relationships are then applied to a particular flood event using the HEC-PBA program. The information is transferred to HEC-PBA from HEC-DAMCAL using HEC-DSS. HEC-DSS is also used to graphically view program inputs and outputs. Selected input for HEC-PBA is directly from HEC-DSS.

The Appendices contain examples of flood damage computations using the procedure described above. Examples of the data used during development of the flood damage analysis package is shown in Appendix B, for the HEC-DAMCAL program, and Appendix C, for the HEC-PBA program. The Appendices also contain example output results.

#### **3.2. Input Requirements**

There are three mechanisms for defining input for flood damage computations. Data from the GIS is used as input to HEC-DAMCAL. The HEC-DAMCAL and HEC-PBA programs both require instructions from an input file.

**(1) GIS Data.** The flood damage computations are determined based on data generated by the (GIS). The Geographic Resources Analysis Support System (GRASS), Version 4.0, was the GIS software used in this exercise.

The information, necessary for flood damage analysis, developed using the GIS are:

- **Damage Reach Designations,**
- **Landuse Classification,**
- **Ground Elevations; and,**
- **Reference Flood Elevations.**

GRASS uses the Relational Information Manager (RIM) to manage its data base. The HEC-DAMCAL program requires a data file in ASCII form which specifies the attributes listed above for each grid cell to be analyzed. After all of the necessary attribute maps have been created, GRASS is able to generate the data file using RIM.

**Damage Reach Designations.** The damage reaches were defined based on the largest possible flood boundary, corporate limits, reservation boundaries and county lines. The flood boundary that would result from failure of Oahe Dam was chosen to define the maximum possible flooded area. Information from the U.S. Census Bureau's TIGER files was used to define the city, county and reservation boundaries.

The damage reach boundaries were digitized using the v.digit program in GRASS. The flood boundary for dam failure was used as the base map. TIGER data was used to overlay the other boundaries. A new vector file was created which divided the flooded area into polygons which represent the damage reaches. A raster map was then generated using GRASS to label all of the grid cells within a polygon with the appropriate damage reach number. The area between Oahe Dam and Big Bend Dam includes 15 damage reaches, as defined in Table 1.

**TABLE 1**  
**Damage Reach Definitions**

| <u>Reach</u> | <u>Reach Definition</u>                               |
|--------------|---|
| 1            | Hughes County, upstream of Pierre.                    |
| 2            | Stanley County, upstream of Fort Pierre.              |
| 3            | City of Pierre.                                       |
| 4            | City of Fort Pierre.                                  |
| 5            | Stanley County, Bad River, upstream of Fort Pierre.   |
| 6            | Stanley County, downstream of Fort Pierre.            |
| 7            | Hughes County, downstream of Pierre to Reservation.   |
| 8            | Stanley County, downstream of Reach 6 to Reservation. |
| 9            | Lower Brule Reservation, Stanley County.              |
| 10           | Crow Creek Reservation, Hughes County.                |
| 11           | Lower Brule Reservation, Lyman County.                |
| 12           | Crow Creek Reservation, Hyde County.                  |
| 13           | Crow Creek Reservation, Buffalo County.               |
| 14           | City of Lower Brule.                                  |
| 15           | City of Fort Thompson.                                |

Landuse Classification. The landuse for this exercise was defined for urban areas and rural areas separately using different methods. It is important to realize that landuse classification can be done many different ways. The landuse classifications used during the development of the flood damage programs should be considered approximate and used for test purposes only. It is recommended that the landuse be reclassified by a qualified analysts to provide more meaningful flood damage computations.

Landuse for the urban areas, Pierre and Fort Pierre, was classified based on aerial photographs at a scale of 1" = 1000'. The photos were converted into GIS format at the Omaha District office. The v.digit program within GRASS was used to divide the urban area into polygons of similar landuse. The flood boundary for dam failure was used as the base map to define the outer edge. The aerial photos were used as a backdrop for the area. A new vector map was created which divided the urban areas into 12 different landuse types. A raster map was then generated from the vector map to label all of the grid cells within each polygon with the appropriate landuse category. The landuse categories for the urban areas are shown in Table 2.

**TABLE 2**  
**Urban Landuse Categories**

| <u>Category</u> | <u>Category Type</u>            |
|-----------------|---------------------------------|
| 1               | Residential                     |
| 2               | Mobile Homes                    |
| 3               | Schools                         |
| 4               | Offices                         |
| 5               | Warehouses                      |
| 6               | Department Stores               |
| 7               | Grocery Stores                  |
| 8               | Motels                          |
| 9               | Industrial                      |
| 10              | Recreation Areas / Golf Courses |
| 11              | Undeveloped Open Area           |
| 12              | Water Bodies                    |

The most difficult classification within the urban areas is for industrial and commercial properties. Categories 5, 6, 7 & 8 were chosen as being representative of typical commercial enterprises. It is important that landuse, and especially industrial and commercial areas, be verified by a qualified economist.

Landuse classification for rural areas was based on the National Oceanic and Atmospheric Administration (NOAA) Advanced Very High Resolution Radiometer (AVHRR) data for land cover characterization in the conterminous United States. The AVHRR data used was originally developed at a spatial resolution of 1 kilometer. Although the data is somewhat crude, it does distinguish between cropland and natural vegetation. The data are also collected frequently which also adds to its accuracy.

The original AVHRR data had 150 land cover categories. The data was reclassified using GRASS for the area within the flood boundary between Oahe and Big Bend Dams. It is necessary to distinguish between cropland and undeveloped land for flood damage computations. Therefore, the land cover was reclassified into 4 categories, as listed in Table 3.

**TABLE 3**  
**Rural Landuse Categories**

| <u>Category</u> | <u>Category Type</u> |
|-----------------|----------------------|
| 1               | Cropland             |
| 2               | Grassland            |
| 3               | Woodland             |
| 4               | Water                |

Ground Elevations. The topographic data, which defines the ground elevations within the study area, was developed at the Omaha District office. The data was not modified prior to being used in the flood damage analysis. It was evident that the data does contain some errors. It is recommended that the topographic data be verified in regard to its relationship with the landuse.

Reference Flood Elevations. The reference flood information was developed using the GIS and HEC-2 output. There are several different floods that could be used to represent the reference flood. The flood elevations associated with a release of 200,000 cfs from Lake Oahe and a pool level of 1423 ft msl at Lake Sharpe was chosen as the reference flood for testing purposes.

A vector file was created using the v.digit program in GRASS. The flood boundary for dam failure was used as the base map and a vector map showing the HEC-2 cross section locations was used as an overlay. The cross section locations were digitized onto the base map along with some intermediate sections. The sections were labeled with the water surface elevations calculated by HEC-2. A raster map was generated from the vector map which labeled those grid cells that fell along the labeled lines. A surface contour algorithm was then used to assign values to the grid cells between cross sections.

The result is a data file in ASCII form which defines the damage reach, landuse classification, ground elevation, and reference flood elevation for each grid cell in the study area. Separate data files are created for urban and rural areas because they are analyzed separately. The data files generated by GRASS are in free format and cannot be used directly by HEC-DAMCAL. A shell script was written which converts the data file into a fixed format for use in HEC-DAMCAL.

**(2) HEC-DAMCAL Input.** The HEC-DAMCAL program requires input from two sources: the GIS and an input file. The input file contains the following types of information:

- Job Control Information,
- Grid Cell Data File Definitions,
- Depth-damage Functions,
- Structure and Content Values,
- Landuse Densities,
- Damage Reach Information; and,
- Single Event Flood Elevations (optional).

Job control information specifies the number of reaches to be analyzed, number of landuse conditions and output specifications. Definitions for the data file includes the size of the file (rows and columns), number of grid cells, physical size of the grid cells (acres) and how the data file is formatted.

Depth-damage functions define the potential damage to structures and contents as a percentage of their value for a range of flood depths. Structure values are specified in terms of an average for the particular land use type. Content values can be specified in dollars or as a percentage of the structure value. Landuse density is specified based on the average number of structures per grid cell for a particular landuse type.

**Damage reach information includes a reach label, elevation of the reference flood at the index location and the range of elevation values to be analyzed. Damages for single flood events can be analyzed by specifying the flood elevations at the index location for each event.**

A more detailed description of the format and definitions of input records for HEC-DAMCAL is contained in the DAMCAL User's Manual, dated February 1979, and is available from the Hydrologic Engineering Center, Davis, California.

**(3) HEC-PBA Input.** The HEC-PBA program is separated into two different programs known as the Preprocessor and the Analysis programs. Each program requires different input data. The advantage of having the program divided is that normally the Preprocessor only needs to be run once, unless the landuse crop functions, or other conditions change. If there are no changes, the Analysis program can analyze several different flood events.

The Preprocessor program uses the following data stored in HEC-DSS:

- Elevation-Damage Relationships,
- Elevation-Area Relationships,
- Elevation-Structures Relationships,
- Crop Loss Functions; and,
- Flood Hydrographs.

The elevation-damage, area and structures relationships are output from HEC-DAMCAL. The crop loss functions define the potential crop losses for each crop type throughout the entire year. They are put into HEC-DSS format using DSSPD, which was developed for entering paired data. Flood hydrographs are usually input to HEC-DSS by a rainfall-runoff model such as HEC-1.

The Preprocessor program requires the following information in its input file:

- Job Control Information,
- Boundary Definitions,
- Crop Production and Market Statistics,
- Damage Reach Information; and,
- Project Information (optional).

Job control information specifies the type of output desired. Boundary definitions are used to aggregate damages within specified political boundaries such as communities, Counties, Corps Districts, Congressional Districts and Flood Control Districts. These boundaries do not necessarily correspond to damage reach boundaries. There may be several damage reaches within a single political boundary.

Crop production and market statistics specify the planting dates, average annual yield, average market price and harvest costs for each crop type. The spatial distribution of crops must also be specified. The distribution is usually specified as a percentage of the total cropland being planted in a particular crop within each damage reach; however, the actual area planted in a particular crop can also be specified.

**Damage reach information specifies a label for the reach, the political boundaries within the reach and the appropriate hydrographs for the reach. The flood stage must also be specified as the elevation at which damages begin within each reach. It is important that the damage reach designations be exactly the same as those defined in the HEC-DAMCAL program.**

**Project information for levees and/or reservoirs may be specified if the user is interested in analyzing both with- and without-project conditions. The program allocates benefits to one or several projects based on a reduction in damages and a weighting scheme defined by the user.**

**The Analysis program requires little input. The following is a list of the necessary input:**

- **Job Specifications,**
- **Period of Analysis,**
- **Project Benefit Allocations for Reservoirs (optional); and,**
- **Summary Report Table Selection.**

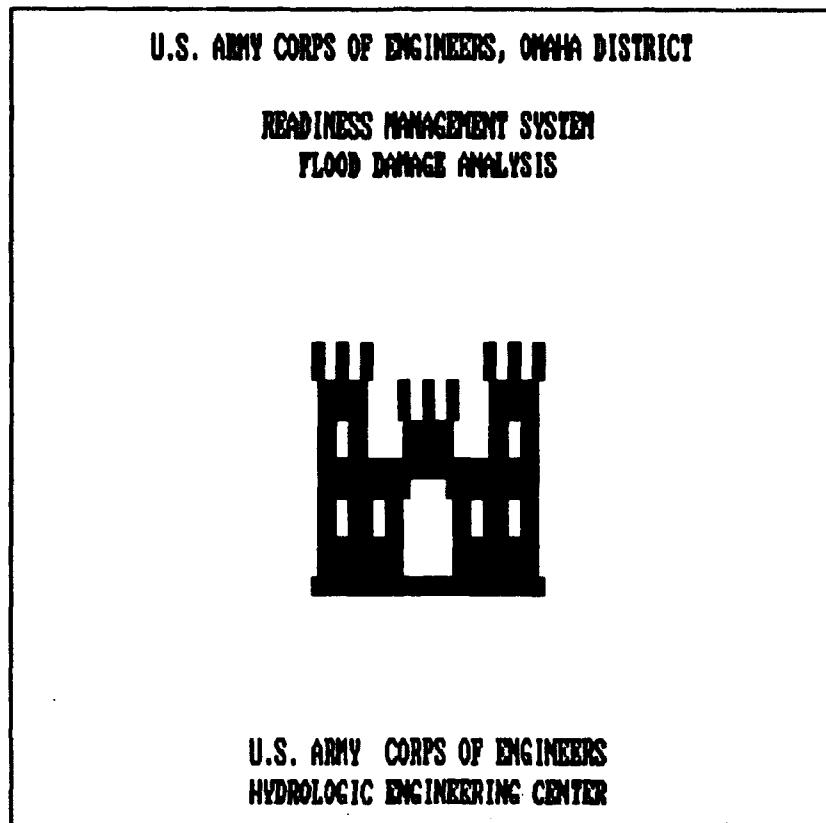

**Job specifications define output options and allow for adjustment of crop market values using price index factors. The period of analysis is specified by beginning date, ending date and look-back date. Project benefit allocation for reservoir is specified as a percentage of the total benefits for each project. Summary report table selection can be based on any of the political boundaries and/or damage reach boundaries.**

**A more detailed description of the format and input records for both the Preprocessor and the Analysis programs will be contained in the HEC-PBA User's Manual. The manual is expected to be published in the Fall of 1992. It will be available from the Hydrologic Engineering Center, Davis, California.**

### **3.3. Program Operation**

**This section describes how the flood damage programs are operated. The process has been automated by using screens, macros and batch files to create a menu driven interface which makes it easy to use. The screens are shown in this section along with brief definitions of each command.**

Screen 1 - Banner

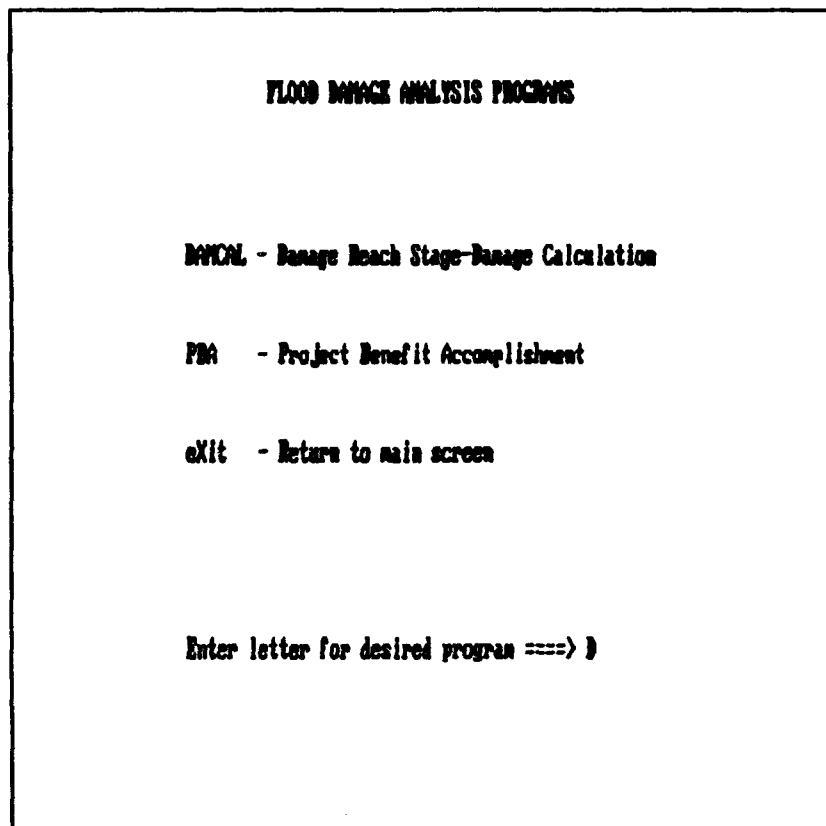

The following commands can be used with this screen:

<ENTER> - Continue to the next screen.

" X " - Exit the flood damage analysis.

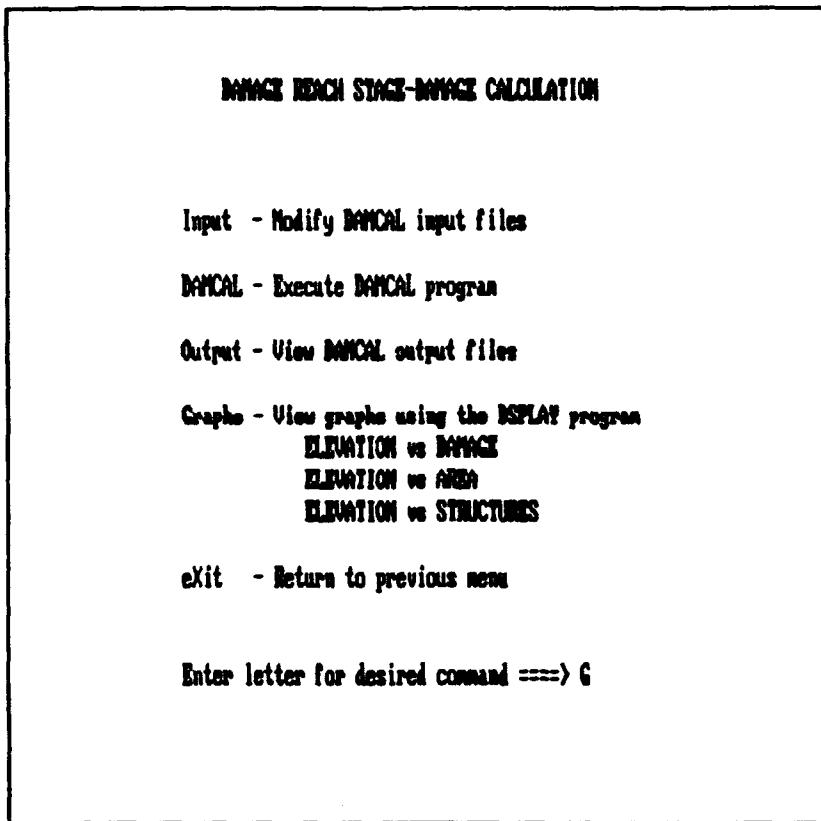

## Screen 2 - Flood Damage Program Choice

The following commands can be used with this screen:

- " D " - Choose the HEC-DAMCAL program options. From there the user is able to perform the operations necessary for executing the HEC-DAMCAL program.
- " P " - Choose the HEC-PBA program options. From there the user is able to perform the operations necessary for executing the HEC-PBA program.
- " X " - Exit to the Banner screen.

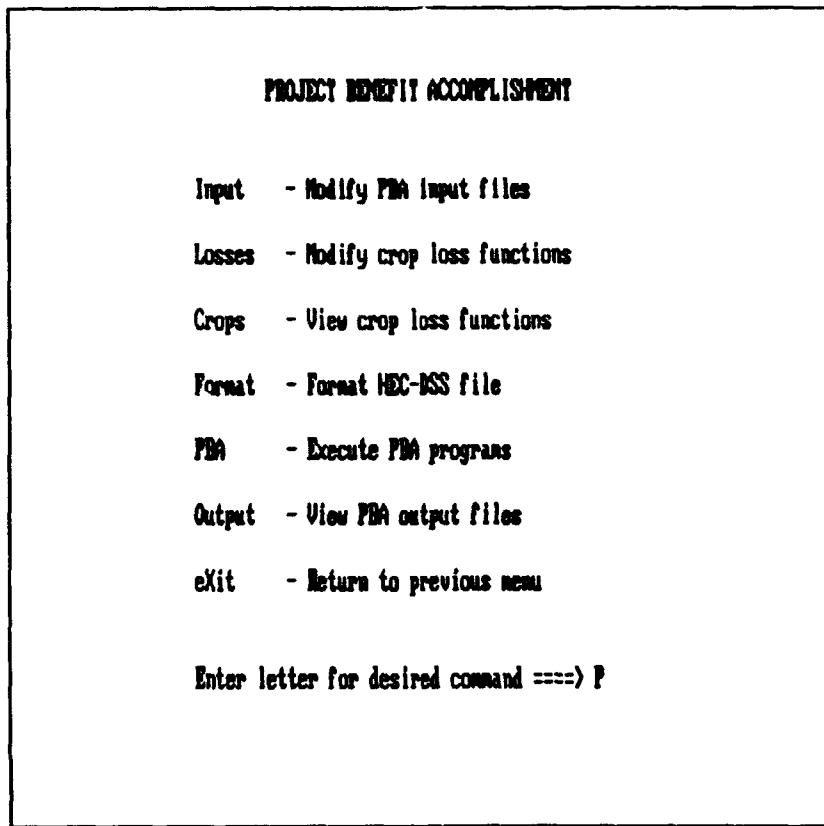

Screen 3 - Selections for executing the HEC-DAMCAL Program

The following commands can be used with this screen:

- " I " - Allows the user to edit the input files for HEC-DAMCAL using the COED editor. The user chooses the input for urban areas or agricultural areas.
- " D " - Executes the HEC-DAMCAL program. The user chooses to compute urban damages or agricultural damages.
- " O " - Allows the user to view the HEC-DAMCAL output files using the LIST program. The user chooses to view output for urban areas or agricultural areas.
- " G " - Executes the DSPLAY program to allow the elevation-damage, area or structures relationships to be viewed graphically. The user must specify the river name, reach number, landuse type (URBAN or AGRICULTURAL) and landuse condition (EXISTING, FUTURE or MODIFIED). All entries must be UPPERCASE.
- " X " - Exits to the Program Selection screen.

Screen 4 - Selections for executing the HEC-PBA Program

The following commands can be used with this screen:

- " I " - Allows the user to edit the HEC-PBA input files using the COED editor. The user must specify input for the Preprocessor program or input for the Analysis program.
- " L " - Allows the user to edit the crop loss functions using the DSSUTL program. New crop loss functions must be entered externally using the DSSPD program.
- " C " - Executes the DSPLAY program to allow crop loss functions to be viewed graphically. The user must specify the crop type. All entries must be UPPERCASE.
- " F " - Reformats the HEC-DSS file using HEC-MATHPK.
- " P " - Execute the HEC-PBA program. The user must choose the Preprocessor or Analysis program.
- " O " - Allows the user to view the HEC-PBA output files using the LIST program.
- " X " - Exits to the Program Selection screen.

### **3.4. Output Capabilities**

There are two types of output from the flood damage computations. They are Damage Summary Reports and Graphical Displays. HEC-DAMCAL generates output in HEC-DSS format which can be viewed graphically. HEC-PBA provides only Damage Summary Reports.

**(1) Damage Summary Reports.** Both the HEC-DAMCAL and HEC-PBA programs provide summary reports. The reports can be viewed on the screen or printed out for documentation purposes.

The output from HEC-DAMCAL lists the stage-damage, elevation-damage, elevation-structures and elevation-area relationships in tabular form for all of the landuse categories and for each damage reach. The program also lists total the damage, structures flooded, and area flooded for single flood events if that option is used. The HEC-DAMCAL output tends to be lengthy because it restates many of the input definitions.

The output from HEC-PBA comes in two forms, the Preprocessor output and the Analysis output. Normally, once the Preprocessor output is verified, there is no need to generate another report unless some function or conditions change. The most meaningful output, in terms of summary reports, comes from the Analysis program. It lists the damage values for each damage reach, each damage categories (land-use) category, and each boundary specified. The Analysis output lists urban and agricultural damages separately. The program also defines damages throughout the range of elevations (zones) defined by the hydrographs for both with- and without-project conditions.

**(2) Graphical Displays.** Output from the HEC-DAMCAL program is best interpreted by viewing it graphically. The elevation-damage, area and structures flooded relationships can all be viewed using the DSPLAY program. Graphical displays are useful for detecting anomalies in the results. The DSPLAY program is limited to 7 curves per plot, and in some cases all of the damage categories (land use) categories cannot be viewed.

It is useful to view the crop loss functions used by HEC-PBA graphically. If these functions do not appear to be similar in form to the typical crop loss function, the HEC-PBA program will not provide meaningful results. The flood hydrographs can also be viewed to verify beginning and ending dates to be used in the analysis.

## APPENDIX B

### STUDY EXAMPLE

#### **B-1. Study Description**

The study area includes all of the property from Oahe Dam to Big Bend Dam in South Dakota, that lies within the flood boundary that would result from failure of Oahe Dam. The sample data was developed at the Hydrologic Engineering Center (HEC) with the exception of the flood boundary, the original AVHRR data and the Digital Elevation Model (DEM), which were developed at the Omaha District office.

The flood event analyzed was based on a release of 200,000 cfs from Lake Oahe with a pool elevation of 1423 ft msl at Lake Sharpe. All of the damage reaches, as defined in Table 1, were analyzed with the exception of reaches 5, 14 and 15. These reaches were excluded because of a lack of data.

#### **B-2. Input Data**

##### **(1) Economic data for Urban Areas**

Economic input data generated using the GIS is shown in Appendix B Section 1. The original data file generated by GRASS is in a free format. A shell script titled "form" is used to reformat the data into a fixed format as shown in the Appendix. The user simply types:

```
form [Input filename] [Output filename] to reformat the data base file.
```

Structure and content values were estimated using little information. As stated in section III, it is essential that the landuse classification, including all of the necessary economic data, be verified by a qualified economist to ensure more accurate results. The data developed at HEC is intended to be used for test purposes only. The composite damage functions, which define the depth-damage relationships, for the urban land use categories described in Table 2 were obtained from the Economics Branch of Planning Division at the Omaha District office. The functions were modified to include depths greater than 10 feet by a simple linear extrapolation. The composite damage functions, structure and content values are listed in the HEC-DAMCAL input file in Appendix B Section 2 and summarized in the HEC-DAMCAL output file in Appendix B Section 3.

##### **(2) Economic Data for Agricultural Areas**

The South Dakota Agricultural Statistics Service and South Dakota State University were contacted to obtain information on crop planting dates, crop production statistics, harvest costs and market values. The information provided was based on the 1990-1991

crop year, and was used to develop all of the necessary data for flood damage computations.

Crop loss functions were developed based on the average planting and harvest dates for the study area. Crop densities were based on production statistics for each county. It was found that 87 percent of the entire area was comprised of combinations of wheat, corn oats and sorghum. Soybeans and sunflowers comprised the other 13 percent and were neglected in this analysis. The crop loss functions used in the analysis are shown with the HEC-PBA input in Appendix D Section 2.

Market statistics, crop prices and yields, for the crops mentioned above were based on average values for the entire state. Harvest costs were estimated based on information from the Agricultural Economics Department at South Dakota State University. Harvest costs were based on average fees charged by commercial harvester. Hauling fees were also included. The economic data for agricultural areas used in the analysis is listed in the HEC-PBA Preprocessor input file in Appendix C Section 1 and is summarized in the HEC-PBA Preprocessor output file in Appendix D Section 4.

### (3) Flood Hydrographs

A simple triangular hydrograph with a peak stage of 1435 ft msl and a duration of 7 days was used to calculate damages in the cities of Pierre and Fort Pierre, as well as the agricultural areas upstream. Another simplified hydrograph with a peak stage of 1423 ft msl and a duration of 7 days was used to calculate damages for the agricultural areas around Lake Sharpe. The hydrographs are shown in Appendix D Section 3 with the input data for HEC-PBA.

## B-3. Output Data

### (1) Output from HEC-DAMCAL

Sample output from the HEC-DAMCAL program is shown in Appendix C Section 1. The report generated by the program is shown along with examples of the elevation-damage, elevation-area and elevation-structures flooded relationships. The plots shown in Appendix C Section 4 were generated using the DSPLAY program. The HEC-DAMCAL results were reviewed to confirm that the program is operating properly and writing the elevation relationships to HEC-DSS properly. The results were not thoroughly reviewed for accuracy because of the limitations in the accuracy of the input data.

### (2) Output from HEC-PBA

Sample output from the HEC-PBA program is shown in Appendix D Section 4. The Preprocessor output summarizes all of the original input data from its input file and from HEC-DSS. The Preprocessor output does not list flood damage values. These are listed in the output from the HEC-PBA Analysis program. The Analysis output lists damages by reaches and specific boundaries. Damages are listed for agricultural areas and urban areas separately for both with- and without-project conditions. There is no graphical output from HEC-PBA.

The results from HEC-PBA were verified by comparison with output from HEC-DAMCAL for single flood events. The results were not reviewed for accuracy in terms of providing meaningful estimates of damages because of the inaccuracies in the input data. The program will provide more meaningful results when better data is used.
